

# GUROBI OPTIMIZER EXAMPLE TOUR

Version 9.0, Copyright © 2019, Gurobi Optimization, LLC

<b>1</b>	<b>Introduction</b>	<b>1</b>
<b>2</b>	<b>Example tour</b>	<b>2</b>
2.1	A list of the Gurobi examples . . . . .	3
2.2	Load and solve a model from a file . . . . .	6
2.3	Build a model . . . . .	7
2.4	Additional modeling elements . . . . .	9
2.5	Modify a model . . . . .	10
2.6	Change parameters . . . . .	12
2.7	Automated parameter tuning . . . . .	12
2.8	Diagnose and cope with infeasibility . . . . .	13
2.9	MIP starts . . . . .	14
2.10	Model-data separation in Python . . . . .	15
2.11	Callbacks . . . . .	16
<b>3</b>	<b>Example Source Code</b>	<b>17</b>
3.1	C Examples . . . . .	17
	batchmode_c.c . . . . .	17
	bilinear_c.c . . . . .	23

The Gurobi<sup>TM</sup> distribution includes an extensive set of examples that illustrate commonly used features of the Gurobi libraries. Most examples have versions for C, C++, C#, Java, Visual Basic, and Python. A few, however, illustrate features that are specific to the Python interface.

The distribution also includes examples for our MATLAB® and R interfaces. Note, however, that our interfaces to these languages are built around the assumption that you will use the rich matrix-oriented capabilities of the underlying languages to build your optimization models. Thus, our examples for these languages don't attempt to show you how to build models. We have instead chosen to provide a few simple examples that demonstrate how to pass matrices into our interface.

This document provides a brief tour of these examples. We won't go through each example in detail. Instead, we'll start with an [Overview](#) of the set of tasks that you are likely to want to perform with the Gurobi Optimizer. Later sections will then describe how specific examples accomplish each of these tasks. Alternatively, we provide a [Structured List](#) of all of our examples, which you can use to dive directly into an example of interest to you. In either case, we suggest that you browse the example source code (in a text editor, or in another browser window) while reading this document. This document includes [Source Code](#) for all of the examples, in all available languages. Source files are also available in the `examples` directory of the Gurobi distribution.

If you would like further details on any of the Gurobi routines used in these examples, please consult the [Gurobi Reference Manual](#).

This document provides a quick guided tour of the Gurobi examples; we will try to highlight some of the most important features of these examples. Full source code is provided in this document, so you are free to explore the examples in full detail.

Wherever possible, we try to discuss the examples in a manner that is independent of programming languages. We will refer to each example using a brief, language independent name. You will need to map this name to the specific source file name for your language. For example, the `facility` example corresponds to six different implementations, one in C (`facility_c.c`), one in C++ (`facility_c++.cpp`), one in Java (`Facility.java`), one in C# (`facility_cs.cs`), one in Visual Basic (`facility_vb.vb`), and one in Python (`facility.py`). If you would like to look at the language implementation for a particular example, please refer to the appropriate example source file.

### Topics covered in the examples

The easiest place to start your introduction to the Gurobi examples is probably with the examples that [load and solve a model from a file](#). These demonstrate the most basic capabilities of the Gurobi libraries. They also demonstrate the use of model attributes, which are an important concept in the Gurobi optimizer.

Once you are comfortable with these examples, you should move on to the examples that [build a model](#) from scratch. These show you how to create variables and constraints, and add them to an optimization model.

The next topic covered in this document is [model modification](#). The Gurobi distribution includes examples that add and remove constraints, add variables, and change variable types, bounds and objective coefficients. You modify a model in much the same way that you build a model from scratch, but there are some important differences involving the use of the solution information.

Next, this document covers [parameter changes](#). The `params` example shows you how to change parameters, and in particular how to use different parameter settings for different models.

On a related note, the [tuning](#) section demonstrates the use of our automated tuning tool. This tool searches for parameter settings that improve performance on a particular model.

The [infeasibility](#) section considers a few examples that cope with model infeasibility. Some use an Irreducible Inconsistent Subsystem (IIS) to handle the infeasibility, while others relax constraints.

One useful MIP feature that is worth understanding is [MIP starts](#). A MIP start allows you to specify a known feasible solution to the MIP solver. The solution provides a bound on the objective of the best possible solution, which can help to limit the MIP search. The solution also provides a potential start point for the local search heuristics that are utilized by the Gurobi MIP solver.

It is possible to achieve model-data separation when using our Python interface, as is often done in modeling languages, but you need to make use of Python modules to do so. The [model-data separation](#) section provides an example of how this is done. It considers three versions of the diet example. All three use the same function to formulate and solve the actual optimization model, but they obtain model data from very different places.

The final topic we cover in this document is [Gurobi callbacks](#). Callbacks allow the user to obtain periodic progress information related to the optimization.

## 2.1 A list of the Gurobi examples

We recommend that you begin by reading the overview of the examples (which begins in the [next section](#)). However, if you'd like to dive directly into a specific example, the following is a list of all of the examples included in the Gurobi distribution, organized by basic function. The source for the examples can be found by following the provided links, or in the `examples` directory of the Gurobi distribution.

### Read a model from a file

- **lp** - A very simple example that reads a continuous model from a file, optimizes it, and writes the solution to a file. If the model is infeasible, it writes an Irreducible Inconsistent Subsystem (IIS) instead. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [R](#), [VB](#).
- **mip2** - Reads a MIP model from a file, optimizes it, and then solves the fixed version of the MIP model. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [VB](#).

### Build a simple model

- **mip1** - Builds a trivial MIP model, solves it, and prints the solution. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **qp** - Builds a trivial QP model, solves it, converts it to an MIQP model, and solves it again. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **qcp** - Builds and solves a trivial QCP model. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **bilinear** - Builds and solves a trivial bilinear model. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **sos** - Builds and solves a trivial SOS model. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **dense** - Solves a model stored using dense matrices. We don't recommend using dense matrices, but this example may be helpful if your data is already in this format. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [VB](#).
- **genconstr** - Demonstrates the use of simple general constraints. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **matrix1** - Python-only example that illustrates the matrix-oriented Python interface. [matrix1.py](#).
- **multiobj** - Demonstrates the use of multi-objective optimization. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **piecewise** - Demonstrates the use of piecewise-linear objective functions. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).

- **gc\_pwl** - Demonstrates the use of piecewise-linear constraint. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **gc\_pwl\_func** - Demonstrates the use of function constraints. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **poolsearch** - Demonstrates the use of solution pools. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).

## A few simple applications

- **diet** - Builds and solves the classic diet problem. Demonstrates model construction and simple model modification - after the initial model is solved, a constraint is added to limit the number of dairy servings. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **diet2**, **diet3**, **diet4**, **dietmodel** - Python-only variants of the diet example that illustrate model-data separation. [diet2.py](#), [diet3.py](#), [diet4.py](#), [dietmodel.py](#).
- **facility** - Simple facility location model: given a set of plants and a set of warehouses, with transportation costs between them, this example finds the least expensive set of plants to open in order to satisfy product demand. This example demonstrates the use of MIP starts -- the example computes an initial, heuristic solution and passes that solution to the MIP solver. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **matrix2** - Python-only example that solves the n-queens problem using the matrix-oriented Python interface. [matrix2.py](#).
- **netflow** - A Python-only example that solves a multi-commodity network flow model. It demonstrates the use of several Python modeling constructs, including dictionaries, tuples, tuple dict, and tuple list objects. [netflow.py](#).
- **portfolio** - A Python-only example that solves a financial portfolio optimization model, where the historical return data is stored using the pandas package and the result is plotted using the matplotlib package. It demonstrates the use of pandas, NumPy, and Matplotlib in conjunction with Gurobi. [portfolio.py](#).
- **sudoku** - Reads a Sudoku puzzle dataset from a file, builds a MIP model to solve that model, solves it, and prints the solution. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **workforce1** - Formulates and solves a workforce scheduling model. If the model is infeasible, the example computes and prints an Irreducible Inconsistent Subsystem (IIS). [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **workforce2** - An enhancement of **workforce1**. This example solves the same workforce scheduling model, but if the model is infeasible, it computes an IIS, removes one of the associated constraints from the model, and re-solves. This process is repeated until the model becomes feasible. Demonstrates constraint removal. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).

- **workforce3** - A different enhancement of **workforce1**. This example solves the same workforce scheduling model, but if the model is infeasible, it adds artificial variables to each constraint and minimizes the sum of the artificial variables. This corresponds to finding the minimum total change in the right-hand side vector required in order to make the model feasible. Demonstrates variable addition. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **workforce4** - An enhancement of **workforce3**. This example solves the same workforce scheduling model, but it starts with artificial variables in each constraint. It first minimizes the sum of the artificial variables. Then, it introduces a new quadratic objective to balance the workload among the workers. Demonstrates optimization with multiple objective functions. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **workforce5** - An alternative enhancement of **workforce3**. This example solves the same workforce scheduling model, but it starts with artificial variables in each constraint. It formulates a multi-objective model where the primary objective is to minimize the sum of the artificial variables (uncovered shifts), and the secondary objective is to minimize the maximum difference in the number of shifts worked between any pair of workers. Demonstrates multi-objective optimization. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).

### Illustrating specific features

- **feasopt** - Reads a MIP model from a file, adds artificial slack variables to relax each constraint, and then minimizes the sum of the artificial variables. It then computes the same relaxation using the *feasibility relaxation* feature. The example demonstrates simple model modification by adding slack variables. It also demonstrates the feasibility relaxation feature. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **lpmethod** - Demonstrates the use of different LP algorithms. Reads a continuous model from a file and solves it using multiple algorithms, reporting which is the quickest for that model. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **lpmod** - Demonstrates the use of advanced starts in LP. Reads a continuous model from a file, solves it, and then modifies one variable bound. The resulting model is then solved in two different ways: starting from the solution of the original model, or restarting from scratch. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **params** - Demonstrates the use of Gurobi parameters. Reads a MIP model from a file, and then spends 5 seconds solving the model with each of four different values of the **MIPFocus** parameter. It compares the optimality gaps for the four different runs, and continues with the **MIPFocus** value that produced the smallest gap. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **sensitivity** - MIP sensitivity analysis. Reads a MIP model, solves it, and then computes the objective impact of fixing each binary variable in the model to 0 or 1. Demonstrates the multi-scenario feature. [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **tune** - Uses the parameter tuning tool to search for improved parameter settings for a model. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [VB](#).

- **fixanddive** - Implements a simple MIP heuristic. It reads a MIP model from a file, relaxes the integrality conditions, and then solves the relaxation. It then chooses a set of integer variables that take integer or nearly integer values in the relaxation, fixes them to the nearest integer, and solves the relaxation again. This process is repeated until the relaxation is either integer feasible or linearly infeasible. The example demonstrates different types of model modification (relaxing integrality conditions, changing variable bounds, etc.). [C](#), [C++](#), [C#](#), [Java](#), [MATLAB](#), [Python](#), [R](#), [VB](#).
- **multiscenario** - Simple facility location model: given a set of plants and a set of warehouses, with transportation costs between them, this example finds the least expensive set of plants to open in order to satisfy product demand. Since the plant fixed costs and the warehouse demands are uncertain, multiple scenarios are created to capture different possible values. A multi-scenario model is constructed and solved, and the solutions for the different scenarios are retrieved and displayed. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [VB](#).
- **batchmode** - Demonstrates the use of batch optimization. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [VB](#).
- **workforce\_batchmode** - Python-only example which formulates a workforce scheduling model. The model is solved using batch optimization. The VTag attribute is used to identify the set of variables whose solution information is needed to construct the schedule. [workforce\\_batchmode.py](#).

- **callback** - Demonstrates the use of Gurobi callbacks. [C](#), [C++](#), [C#](#), [Java](#), [Python](#), [VB](#).

## 2.2 Load and solve a model from a file

**Examples:** batchmode, callback, feaso, fixanddive, lp, lpmethod, lpmod, mip2, params, sensitivity

One of the most basic tasks you can perform with the Gurobi libraries is to read a model from a file, optimize it, and report the result. The `lp` ([lp\\_c.c](#), [lp\\_c++.cpp](#), [lp\\_cs.cs](#), [Lp.java](#), [lp.py](#), [lp\\_vb.vb](#)) and `mip2` ([mip2\\_c.c](#), [mip2\\_c++.cpp](#), [mip2\\_cs.cs](#), [Mip2.java](#), [mip2.m](#), [mip2.py](#), [mip2.R](#), [mip2\\_vb.vb](#)) examples are simple illustrations of how this is done in the various supported Gurobi languages. While the specifics vary from one language to another, the basic structure remains the same for all languages.

After initializing the Gurobi environment, the examples begin by reading the model from the specified file. In C, you call the `GRBreadmodel()` function:

```
error = GRBreadmodel(masterenv, argv[1], &model);
```

In C++, this is done by constructing a `GRBModel` object:

```
GRBModel model = GRBModel(env, argv[1]);
```

In C# and Java, this is also done by constructing a `GRBModel` object:

```
GRBModel model = new GRBModel(env, args[0]);
```

In Python, this is done via the `read` global function:

```
model = read(sys.argv[1])
```

The next step is to invoke the Gurobi optimizer on the model. In C, you call `GRBoptimize()` on the `model` variable:

```
error = GRBoptimize(model);
```

In C++, Java, and Python, this is accomplished by calling the `optimize` method on the `model` object:

```
model.optimize();
```

In C#, the first letter of the method name is capitalized:

```
model.Optimize();
```

A successful `optimize` call populates a set of solution attributes in the model. For example, once the call completes, the `X` variable attribute contains the solution value for each variable. Similarly, for continuous models, the `Pi` constraint attribute contains the dual value for each constraint.

The examples then retrieve the value of the model `Status` attribute to determine the result of the optimization. In the `lp` example, an optimal solution is written to a solution file (`model.sol`).

There are many other things you can do once you have read and solved the model. For example, `lp` checks the solution status -- which is highly recommended. If the model is found to be infeasible, this example computes an Irreducible Inconsistent Subsystem (IIS) to isolate the source of the infeasibility.

## 2.3 Build a model

**Examples:** `bilinear`, `diet`, `facility`, `gc_pwl`, `gc_pwl_func`, `genconstr`, `matrix1`, `mip1`, `multiobj`, `multiscenario`, `piecewise`, `poolsearch`, `qcp`, `qp`, `sensitivity`, `sos`, `sudoku`, `workforce1`, `workforce_batchmode`, `workforce2`, `workforce3`, `workforce4`, `workforce5`

Several of the Gurobi examples build models from scratch. We start by focusing on two: `mip1` and `sos`. Both build very simple models to illustrate the basic process.

Typically, the first step in building a model is to create an empty model. This is done using the `GRBnewmodel` function in C:

```
error = GRBnewmodel(env, &model, "mip1", 0, NULL, NULL, NULL, NULL);
```

You can optionally create a set of variables when you create the model, as well as specifying bounds, objective coefficients, and names for these variables. These examples add new variables separately.

In C++, C#, and Java, you create a new model using the `GRBModel` constructor. In Java, this looks like:

```
GRBModel model = new GRBModel(env);
```

In Python, the class is called `Model`, and its constructor is similar to the `GRBModel` constructor for C++ and Java.

Once the model has been created, the typical next step is to add variables. In C, you use the `GRBaddvars` function to add one or more variables:

```
error = GRBaddvars(model, 3, 0, NULL, NULL, NULL, obj, NULL, NULL, vtype, NULL);
```

In C++, Java, and Python, you use the `addVar` method on the `Model` object (`AddVar` in C#). In Java, this looks like:

```
GRBVar x = model.addVar(0.0, 1.0, -1.0, GRB.BINARY, "x");
```

The new variable's lower bound, upper bound, objective coefficient, type, and name are specified as arguments. In C++ and Python, you can omit these arguments and use default values; see the [Gurobi Reference Manual](#) for details.

The next step is to add constraints to the model. Linear constraints are added through the `GRBaddconstr` function in C:

```
error = GRBaddconstr(model, 3, ind, val, GRB_LESS_EQUAL, 4.0, "c0");
```

To add a linear constraint in C, you must specify a list of variable indices and coefficients for the left-hand side, a sense for the constraint (e.g., `GRB_LESS_EQUAL`), and a right-hand side constant. You can also give the constraint a name; if you omit the name, Gurobi will assign a default name for the constraint.

In C++, C#, Java, and Python, you build a linear constraint by first building linear expressions for the left- and right-hand sides. In Java, which doesn't support operator overloading, you build an expression as follows:

```
GRBLinExpr expr = new GRBLinExpr();  
expr.addTerm(1.0, x); expr.addTerm(2.0, y); expr.addTerm(3.0, z);
```

You then use the `addConstr` method on the `GRBModel` object to add a constraint using these linear expressions for the left- and right-hand sides:

```
model.addConstr(expr, GRB_LESS_EQUAL, 4.0, "c0");
```

For C++, C#, and Python, the standard mathematical operators such as `+`, `*`, `<=` have been overloaded so that the linear expression resembles a traditional mathematical expression. In C++:

```
model.addConstr(x + 2 * y + 3 * z <= 4, "c0");
```

Once the model has been built, the typical next step is to optimize it (using `GRBoptimize` in C, `model.optimize` in C++, Java, and Python, or `model.Optimize` in C#). You can then query the `X` attribute on the variables to retrieve the solution (and the `VarName` attribute to retrieve the variable name for each variable). In C, the `X` attribute is retrieved as follows:

```
error = GRBgetdblattrarray(model, GRB_DBL_ATTR_X, 0, 3, sol);
```

In C++:

```

cout << x.get(GRB_StringAttr_VarName) << " "
    << x.get(GRB_DoubleAttr_X) << endl;
cout << y.get(GRB_StringAttr_VarName) << " "
    << y.get(GRB_DoubleAttr_X) << endl;
cout << z.get(GRB_StringAttr_VarName) << " "
    << z.get(GRB_DoubleAttr_X) << endl;

```

In Java:

```

System.out.println(x.get(GRB.StringAttr.VarName) +
    " " + x.get(GRB.DoubleAttr.X));
System.out.println(y.get(GRB.StringAttr.VarName) +
    " " + y.get(GRB.DoubleAttr.X));
System.out.println(z.get(GRB.StringAttr.VarName) +
    " " + z.get(GRB.DoubleAttr.X));

```

In C#:

```

Console.WriteLine(x.Get(GRB.StringAttr.VarName) +
    " " + x.Get(GRB.DoubleAttr.X));
Console.WriteLine(y.Get(GRB.StringAttr.VarName) +
    " " + y.Get(GRB.DoubleAttr.X));
Console.WriteLine(z.Get(GRB.StringAttr.VarName) +
    " " + z.Get(GRB.DoubleAttr.X));

```

In Python:

```

for v in m.getVars():
    print(v.varName, v.x)

```

When querying or modifying attribute values for an array of constraints or variables, it is generally more efficient to perform the action on the whole array at once. This is quite natural in the C interface, where most of the attribute routines take array arguments. In the C++, C#, Java, and Python interfaces, you can use the `get` and `set` methods on the `GRBModel` object to work directly with arrays of attribute values (`getAttr/setAttr` in Python). In the `sudoku` Java example, this is done as follows:

```

double[] [] [] x = model.get(GRB.DoubleAttr.X, vars);

```

We should point out one important subtlety in our interface. We use a *lazy update* approach to building and modifying a model. When you make changes, they are added to a queue. The queue is only flushed when you optimize the model (or write it to a file). In the uncommon situation where you want to query information about your model before optimizing it, you should call the *update* method before making your query.

## 2.4 Additional modeling elements

**Examples:** `bilinear`, `gc_pwl`, `gc_pwl_func`, `genconstr`, `multiobj`, `multiscenario`, `piecewise`, `qcp`, `qp`, `sensitivity`, `sos`

A mathematical programming model in its traditional form consists of a linear objective, a set of linear constraints, and a set of continuous or integer decision variables. Gurobi supports a number of additional modeling constructs. In addition to linear constraints, Gurobi also supports SOS constraints, quadratic constraints, and general constraints. In addition to a single linear objective, Gurobi also supports quadratic objectives, piecewise-linear objectives, and multiple linear objectives. Consult the corresponding examples from the Gurobi distribution for simple examples of how to use each of these modeling elements.

## 2.5 Modify a model

**Examples:** `diet`, `feasopt`, `fixanddive`, `gc_pwl_func`, `lpmod`, `sensitivity`, `workforce3`, `workforce4`, `workforce5`

This section considers model modification. Modification can take many forms, including adding constraints or variables, deleting constraints or variables, modifying constraint and variable attributes, changing constraint coefficients, etc. The Gurobi examples don't cover all possible modifications, but they cover the most common types.

### diet

This example builds a linear model that solves the classic diet problem: to find the minimum cost diet that satisfies a set of daily nutritional requirements. Once the model has been formulated and solved, it adds an additional constraint to limit the number of servings of dairy products and solves the model again. Let's focus on the model modification.

Adding constraints to a model that has already been solved is no different from adding constraints when constructing an initial model. In Python, we can introduce a limit of 6 dairy servings through the following constraint:

```
m.addConstr(buy['milk'] + buy['ice cream'] <= 6, "limit_dairy")
```

For linear models, the previously computed solution can be used as an efficient *warm start* for the modified model. The Gurobi solver retains the previous solution, so the next `optimize` call automatically starts from the previous solution.

### lpmod

Changing a variable bound is also straightforward. The `lpmod` example changes a single variable bound, then re-solves the model in two different ways. A variable bound can be changed by modifying the UB or LB attribute of the variable. In C:

```
error = GRBsetdblattr(element(model, GRB_DBL_ATTR_UB, var, 0.0);
```

In Python:

```
minVar.ub = 0
```

The model is re-solved simply by calling the `optimize` method again. For a continuous model, this starts the optimization from the previous solution. To illustrate the difference when solving the model from an initial, unsolved state, the `lpmod` example calls the `reset` function. In C:

```
error = GRBreset(model, 0);
```

In C++, Java, and Python:

```
m.reset(0)
```

In C#:

```
m.Reset(0)
```

When we call the `optimize` method after resetting the model, optimization starts from scratch. Although the difference in computation time is insignificant for this tiny example, a warm start can make a big difference for larger models.

### **fixanddive**

The `fixanddive` example provides another example of bound modification. In this case, we repeatedly modify a set of variable bounds, utilizing warm starts each time. In C, variables are fixed as follows:

```
for (j = 0; j < nfix; ++j)
{
    fixval = floor(fractional[j].X + 0.5);
    error = GRBsetdblattrelement(model, "LB", fractional[j].index, fixval);
    if (error) goto QUIT;
    error = GRBsetdblattrelement(model, "UB", fractional[j].index, fixval);
    if (error) goto QUIT;
}
```

In Python, they are fixed as follows:

```
for i in range(nfix):
    v = fractional[i]
    fixval = int(v.x + 0.5)
    v.lb = fixval
    v.ub = fixval
```

Again, the subsequent call to `optimize` starts from the previous solution.

### **sensitivity**

The `sensitivity` example computes the optimal objective value associated with fixing each binary variable to 0 or 1. It first solves the given model to optimality. It then constructs a multi-scenario model, where in each scenario a binary variable is fixed to the complement of the value it took in the optimal solution. The resulting multi-scenario model is solved, giving the objective degradation associated with forcing each binary variable off of its optimal value.

### **feasopt**

The last modification example we consider is `feasopt`, which adds variables to existing constraints and also changes the optimization objective. Setting the objective to zero is straightforward: simply call `setObjective` with a zero argument:

```
m.setObjective(0)
```

Adding new variables is somewhat more complex. In the example, we want to add artificial variable(s) to each constraint in order to allow the constraint to be relaxed. We use two artificial variables for equality constraints and one for inequality constraints. The Python code for adding a single artificial variable to constraint `c` is:

```
feasModel.addVar(obj=1.0, name="ArtP_" + c.Constrname, column=Column([1], [c]))
```

We use the `column` argument of the `addVar` method to specify the set of constraints in which the new variable participates, as well as the associated coefficients. In this example, the new variable only participates in the constraint to be relaxed. Default values are used here for all variables attributes except the objective and the variable name.

## 2.6 Change parameters

**Examples:** `batchmode`, `callback`, `fixanddive`, `gc_pwl_func`, `lp`, `lpmethod`, `mip2`, `multiscenario`, `params`, `sensitivity`, `workforce_batchmode`

This section illustrates the use of Gurobi parameters. Example `params` reads a MIP model from a file, then solves the model using four different values of the `MIPFocus` parameter, running for five seconds per value (`MIPFocus` chooses the high-level strategy that the MIP solver uses to solve the problem). It then chooses the parameter value that produced the smallest MIP gap, and continues solving the model until it achieves optimality.

The mechanics of setting a parameter are quite simple. To set the `MIPFocus` parameter in C, do the following:

```
GRBsetintparam(GRBgetenv(model), GRB_INT_PAR_MIPFOCUS, i);
```

In C++:

```
model.set(GRB_IntParam_MIPFocus, i);
```

In Java:

```
model.set(GRB.IntParam.MIPFocus, i);
```

In C#:

```
model.Parameters.MIPFocus = 1
```

or

```
model.Set(GRB.IntParam.MIPFocus, i);
```

In Python:

```
model.Params.MIPFocus = i
```

We should add a comment on how parameter settings propagate between different models. When we set the `TimeLimit` parameter on the base model, then make a copy of that model, the parameter setting is carried over to the copy. When we set the `MIPFocus` parameter on the copy, that parameter change has no effect on the other copies, nor on the original model.

## 2.7 Automated parameter tuning

**Example:** `tune`

The next example we consider is `tune`, which demonstrates the use of our automated parameter tuning tool. This tool searches for parameter settings that improve performance on a model. While

you would typically invoke the tool through the command line, using our `grbtune` program, it can also be invoked from our APIs. We'll provide only a cursory description of the tool here. We recommend that you consult the *Parameter Tuning Tool* section of the [Gurobi Reference Manual](#) for more precise details.

Our tuning example demonstrates a typical use of the tuning tool. You would start by invoking the tool on a model. In C:

```
error = GRBtunemodel(model);
```

In Java:

```
model.tune();
```

This routine solves the model multiple times, with different parameter settings, to find settings that improve performance.

Once tuning is complete, you would then use `GetTuneResult` to retrieve the result. In C:

```
error = GRBgettunerresult(model, 0);
```

In Java:

```
model.getTuneResult(0);
```

The numerical argument indicates which tuning result to retrieve (0 is the best result, 1 is the second-best, etc.). This routine loads the requested parameter set into the environment associated with the argument model.

Once the tune parameter settings have been loaded into the model, you can then call `Optimize` to use these parameters to solve the model, or you can call `Write` to write these parameters to a `.prm` file.

## 2.8 Diagnose and cope with infeasibility

**Examples:** `feasopt`, `lp`, `multiscenario`, `sensitivity`, `workforce1`, `workforce2`, `workforce3`

When solving optimization models, there are some situations where the specified constraints cannot be satisfied. When this happens, you often need to either identify and repair the root cause of the infeasibility, or alternatively find a set of constraints to relax in order to obtain a feasible model. The `workforce1`, `workforce2`, and `workforce3` illustrate these different strategies.

Starting with the simplest of the three examples, `workforce1` formulates a simple workforce scheduling model and solves it. If the model is infeasible, it computes an Irreducible Inconsistent Subsystem (IIS). The user can then inspect this information to understand and hopefully address the source of the infeasibility in the model.

Example `workforce2` is similar, except that if the model is infeasible, the example repeatedly identifies an IIS and removes one of the associated constraints from the model until the model becomes feasible. Note that it is sufficient to remove one constraint from the IIS to address that source of infeasibility, but that one IIS may not capture all sources of infeasibility. It is therefore necessary to repeat the process until the model is feasible.

Example `workforce3` takes a different approach to addressing infeasibility. Rather than identifying and removing IIS members, it allows the constraints of the model to be relaxed. Like the `feasopt` example, an artificial variable is added to each constraint. The example sets the objective

on the original variables to zero, and then solves a model that minimizes the total magnitude of the constraint relaxation.

The `feasopt` example demonstrates another approach to relaxing an infeasible model. It computes a *feasibility relaxation* for the infeasible model. A feasibility relaxation is a model that, when solved, minimizes the amount by which the solution violates the bounds and linear constraints of the original model. This method is invoked as follows:

In C:

```
error = GRBfeasrelax(feasmodel, GRB_FEASRELAX_LINEAR, 1,
                    NULL, NULL, rhspen, &feasobj);
```

In C++:

```
feasmodel1.fasRelax(GRB_FEASRELAX_LINEAR, true, false, true);
```

In C#:

```
feasmodel1.FasRelax(GRB.FEASRELAX_LINEAR, true, false, true);
```

In Java:

```
feasmodel1.fasRelax(GRB.FEASRELAX_LINEAR, true, false, true);
```

In Python:

```
feasmodel1.fasRelaxS(0, True, False, True)
```

The arguments to this method select the objective function for the relaxed model, the specific set of bounds and constraints that are allowed to be relaxed, and the penalties for relaxing specific bounds and constraints.

## 2.9 MIP starts

**Example:** facility, sensitivity

A MIP modeler often knows how to compute a feasible solution to their problem. In cases where the MIP solver is slow in finding an initial feasible solution, it can be helpful for the modeler to provide a feasible solution along with the model itself. This is done through the **Start** attribute on the variables. This is illustrated in the **facility** example.

The **facility** example solves a simple facility location problem. The model contains a set of warehouses, and a set of plants that produce the products required in the warehouses. Each plant has a maximum production capacity and a fixed operating cost. Additionally, there is a cost associated with shipping products from a plant to a warehouse. The goal is to decide which plants should satisfy the demand for the product, given the associated capacities and costs.

The example uses a simple heuristic for choosing an initial solution: it closes the plant with the highest fixed cost. The associated solution may not be optimal, but it could produce a reasonable starting solution for the MIP optimization. The MIP start is passed to the MIP solver by setting the **Start** attribute before the optimization begins. In C, we set the start attribute to open all plants using the following code:

```

/* First, open all plants */
for (p = 0; p < nPlants; ++p)
{
    error = GRBsetdblattrelement(model, "Start", opencol(p), 1.0);
    if (error) goto QUIT;
}

```

In Python:

```

# First open all plants
for p in plants:
    open[p].start = 1.0

```

When you run the example, the MIP solver reports that the start produced a feasible initial solution:

```

User MIP start produced solution with objective 210500 (0.01s)
Loaded user MIP start with objective 210500

```

This initial solution turns out to be optimal for the sample data. Although the computation difference is insignificant for this tiny example, providing a good starting solution can sometimes help for more difficult models.

Note that the MIP start in this example only specifies values for some of the variables -- the variables that determine which plants to leave open and which plants to close. The Gurobi MIP solve uses whatever start information is provided to try to construct a complete solution.

## 2.10 Model-data separation in Python

**Examples:** diet2.py, diet3.py, diet4.py

When building an optimization model in a modeling language, it is typical to separate the optimization model itself from the data used to create an instance of the model. These two model ingredients are often stored in completely different files. We show how a similar result can be achieved in our Python interface with our `diet2.py`, `diet3.py`, and `diet4.py` examples. These examples illustrate alternate approaches to providing data to the optimization model: `diet2.py` embeds the data in the source file, `diet3.py` reads the data from an SQL database (using the Python `sqlite3` package), and `diet4.py` reads the data from an Excel spreadsheet (using the Python `xlrd` package). `dietmodel.py` contains the optimization model itself. The same model is used by `diet2.py`, `diet3.py`, and `diet4.py`.

The key construct that enables the separation of the model from the data is the Python module. A module is simply a set of functions and variables, stored in a file. You import a module into a program using the `import` statement. `diet2.py`, `diet3.py`, and `diet4.py` all populate a set of variables, and then pass them to the `solve` function of the `dietmodel` module using the following pair of statements:

```

import dietmodel
dietmodel.solve(categories, minNutrition, maxNutrition, foods, cost, nutritionValues)

```

The first statement imports the `dietmodel` module, which must be stored in file `dietmodel.py` in the current directory. The second passes the model data to the `solve` function in the newly imported module.

## 2.11 Callbacks

### Example: callback

The final example we consider is **callback**, which demonstrates the use of Gurobi callbacks. Callbacks are used to report on the progress of the optimization or to modify the behavior of the Gurobi solver. To use a callback, the user writes a routine that implements the desired behavior. The routine is passed to the Gurobi optimizer when optimization begins, and the routine is called regularly during the optimization process. One argument of the user routine is a **where** value, which indicates from where in the optimization process the callback is invoked. The user callback routine can call the optimization library to query certain values. We refer the reader to the callback section of the [Gurobi Reference Manual](#) for more precise details.

Our callback example implements a simple termination scheme: the user passes a node count into the callback, and the callback asks the optimizer to terminate when that node count is reached. This is implemented in C as follows:

```
GRBcbget(cbdata, where, GRB_CB_MIP_NODCNT, &nodecnt);
if (nodecnt > limit)
    GRBterminate(model);
```

In Python, this is implemented as:

```
nodecnt = model.cbGet(GRB.Callback.MIP_NODCNT)
if nodecnt > model._mynodelimit:
    model.terminate()
```

To obtain the current node count, the user routine calls the **cbget** routine (the **GRBcbget** function in C, or the **cbGet** method on the model object in C++, C#, Java, and Python).

Our callback example also prints progress information. In C:

```
GRBcbget(cbdata, where, GRB_CB_MIP_NODCNT, &nodecnt);
if (nodecnt - mydata->lastmsg >= 100) {
    ...
    printf("%7.0f ...", nodecnt, ...);
}
```

In Python:

```
nodecnt = model.cbGet(GRB.Callback.MIP_NODCNT)
if nodecnt % 100 == 0:
    print(int(nodecnt), "...")
```

Again, the user callback calls the **cbGet** routine to query the state of the optimization.

We have included source code for all of the distributed examples in this section. The identical example source code is included in the `examples` directory in the Gurobi distribution.

## 3.1 C Examples

This section includes source code for all of the Gurobi C examples. The same source code can be found in the `examples/c` directory of the Gurobi distribution.

### `batchmode_c.c`

```

## callback\_c.c

```

/* Copyright 2019, Gurobi Optimization, LLC */

/*
    This example reads a model from a file, sets up a callback that
    monitors optimization progress and implements a custom
    termination strategy, and outputs progress information to the
    screen and to a log file.

    The termination strategy implemented in this callback stops the
    optimization of a MIP model once at least one of the following two
    conditions have been satisfied:
        1) The optimality gap is less than 10%
        2) At least 10000 nodes have been explored, and an integer feasible
           solution has been found.
    Note that termination is normally handled through Gurobi parameters
    (MIPGap, NodeLimit, etc.). You should only use a callback for
    termination if the available parameters don't capture your desired
    termination criterion.

## gc\_pwl\_c.c

/\* Copyright 2019, Gurobi Optimization, LLC

This example formulates and solves the following simple model  
with PWL constraints:

```
maximize
    sum c[j] * x[j]
subject to
    sum A[i,j] * x[j] <= 0,   for i = 0, ..., m-1
    sum y[j] <= 3
    y[j] = pwl(x[j]),         for j = 0, ..., n-1
    x[j] free, y[j] >= 0,     for j = 0, ..., n-1
where pwl(x) = 0,             if x = 0
              = 1+|x|,        if x != 0
```

Note

```

1.  $\text{sum } \text{pwl}(x[j]) \leq b$  is to bound  $x$  vector and also to favor sparse  $x$  vector.
   Here  $b = 3$  means that at most two  $x[j]$  can be nonzero and if two, then
    $\text{sum } x[j] \leq 1$ 
2.  $\text{pwl}(x)$  jumps from 1 to 0 and from 0 to 1, if  $x$  moves from negative 0 to 0,
   then to positive 0, so we need three points at  $x = 0$ .  $x$  has infinite bounds
   on both sides, the piece defined with two points  $(-1, 2)$  and  $(0, 1)$  can
   extend  $x$  to  $-\infty$ . Overall we can use five points  $(-1, 2)$ ,  $(0, 1)$ ,
    $(0, 0)$ ,  $(0, 1)$  and  $(1, 2)$  to define  $y = \text{pwl}(x)$

**gc\_pwl\_func\_c.c**

```
/* Copyright 2019, Gurobi Optimization, LLC
```

This example considers the following nonconvex nonlinear problem

```
maximize    2 x      + y
subject to   exp(x) + 4 sqrt(y) <= 9
            x, y >= 0
```

We show you two approaches to solve this:

- 1) Use a piecewise-linear approach to handle general function constraints (such as exp and sqrt).
  - a) Add two variables  
u = exp(x)  
v = sqrt(y)
  - b) Compute points (x, u) of u = exp(x) for some step length (e.g., x = 0, 1e-3, 2e-3, ..., xmax) and points (y, v) of v = sqrt(y) for some step length (e.g., y = 0, 1e-3, 2e-3, ..., ymax). We need to compute xmax and ymax (which is easy for this example, but this does not hold in general).
  - c) Use the points to add two general constraints of type piecewise-linear.
- 2) Use the Gurobi's built-in general function constraints directly (EXP and POW). Here, we do not need to compute the points and the maximal possible values, which will be done internally by Gurobi. In this approach, we show how to "zoom in" on the optimal solution and tighten tolerances to improve the solution quality.

```

## genconstr\_c.c

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* In this example we show the use of general constraints for modeling
 * some common expressions. We use as an example a SAT-problem where we
 * want to see if it is possible to satisfy at least four (or all) clauses
 * of the logical for
 *
 * L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
 *      (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
 *      (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
 *      (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)
 *
 * We do this by introducing two variables for each literal (itself and its
 * negated value), a variable for each clause, and then two
 * variables for indicating if we can satisfy four, and another to identify
 * the minimum of the clauses (so if it one, we can satisfy all clauses)
 * and put these two variables in the objective.
 * i.e. the Objective function will be
 *
 * maximize Obj0 + Obj1
 *
 * Obj0 = MIN(Clause1, ... , Clause8)
 * Obj1 = 1 -> Clause1 + ... + Clause8 >= 4
 *
 * thus, the objective value will be two if and only if we can satisfy all
 * clauses; one if and only if at least four clauses can be satisfied, and
 * zero otherwise.

## multiscenario\_c.c

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* Facility location: a company currently ships its product from 5 plants
to 4 warehouses. It is considering closing some plants to reduce
costs. What plant(s) should the company close, in order to minimize
transportation and fixed costs?

Since the plant fixed costs and the warehouse demands are uncertain, a
scenario approach is chosen.

Note that this example is similar to the facility_c.c example. Here we

```

```

    added scenarios in order to illustrate the multi-scenario feature.

    Based on an example from Frontline Systems:
    http://www.solver.com/disfacility.htm
    Used with permission.

```

/*
Sudoku example.

The Sudoku board is a 9x9 grid, which is further divided into a 3x3 grid
of 3x3 grids. Each cell in the grid must take a value from 0 to 9.
No two grid cells in the same row, column, or 3x3 subgrid may take the
same value.

In the MIP formulation, binary variables  $x[i,j,v]$  indicate whether
cell  $\langle i,j \rangle$  takes value 'v'. The constraints are as follows:
1. Each cell must take exactly one value ( $\sum_v x[i,j,v] = 1$ )
2. Each value is used exactly once per row ( $\sum_i x[i,j,v] = 1$ )
3. Each value is used exactly once per column ( $\sum_j x[i,j,v] = 1$ )
4. Each value is used exactly once per 3x3 subgrid ( $\sum_{\text{grid}} x[i,j,v] = 1$ )

Input datasets for this example can be found in examples/data/sudoku*.

## callback\_c++.cpp

```

/* Copyright 2019, Gurobi Optimization, LLC */

/*
    This example reads a model from a file, sets up a callback that
    monitors optimization progress and implements a custom
    termination strategy, and outputs progress information to the
    screen and to a log file.

    The termination strategy implemented in this callback stops the
    optimization of a MIP model once at least one of the following two
    conditions have been satisfied:
        1) The optimality gap is less than 10%
        2) At least 10000 nodes have been explored, and an integer feasible
           solution has been found.

    Note that termination is normally handled through Gurobi parameters
    (MIPGap, NodeLimit, etc.). You should only use a callback for
    termination if the available parameters don't capture your desired
    termination criterion.

## gc\_pwl\_c++.cpp

```
/* Copyright 2019, Gurobi Optimization, LLC
```

This example formulates and solves the following simple model with PWL constraints:

```
maximize
    sum c[j] * x[j]
subject to
    sum A[i,j] * x[j] <= 0,   for i = 0, ..., m-1
    sum y[j] <= 3
    y[j] = pwl(x[j]),         for j = 0, ..., n-1
    x[j] free, y[j] >= 0,     for j = 0, ..., n-1
where pwl(x) = 0,           if x = 0
              = 1+|x|,      if x != 0
```

Note

1. `sum pwl(x[j]) <= b` is to bound `x` vector and also to favor sparse `x` vector. Here `b = 3` means that at most two `x[j]` can be nonzero and if two, then `sum x[j] <= 1`
2. `pwl(x)` jumps from 1 to 0 and from 0 to 1, if `x` moves from negative 0 to 0, then to positive 0, so we need three points at `x = 0`. `x` has infinite bounds on both sides, the piece defined with two points `(-1, 2)` and `(0, 1)` can extend `x` to `-infinite`. Overall we can use five points `(-1, 2)`, `(0, 1)`, `(0, 0)`, `(0, 1)` and `(1, 2)` to define `y = pwl(x)`

```

## gc\_pwl\_func\_c++.cpp

```

/* Copyright 2019, Gurobi Optimization, LLC

```

This example considers the following nonconvex nonlinear problem

```

maximize    2 x      + y
subject to  exp(x) + 4 sqrt(y) <= 9
           x, y >= 0

```

We show you two approaches to solve this:

- 1) Use a piecewise-linear approach to handle general function constraints (such as exp and sqrt).
  - a) Add two variables
 

```

u = exp(x)
v = sqrt(y)

```
  - b) Compute points (x, u) of  $u = \exp(x)$  for some step length (e.g.,  $x = 0, 1e-3, 2e-3, \dots, x_{\max}$ ) and points (y, v) of  $v = \sqrt{y}$  for some step length (e.g.,  $y = 0, 1e-3, 2e-3, \dots, y_{\max}$ ). We need to compute  $x_{\max}$  and  $y_{\max}$  (which is easy for this example, but this does not hold in general).
  - c) Use the points to add two general constraints of type piecewise-linear.
- 2) Use the Gurobi's built-in general function constraints directly (EXP and POW). Here, we do not need to compute the points and the maximal possible values, which will be done internally by Gurobi. In this approach, we show how to "zoom in" on the optimal solution and tighten tolerances to improve the solution quality.

## genconstr\_c++.cpp

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* In this example we show the use of general constraints for modeling
 * some common expressions. We use as an example a SAT-problem where we
 * want to see if it is possible to satisfy at least four (or all) clauses
 * of the logical for
 *
 * L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
 *      (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
 *      (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
 *      (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)
 *
 * We do this by introducing two variables for each literal (itself and its
 * negated value), a variable for each clause, and then two
 * variables for indicating if we can satisfy four, and another to identify
 * the minimum of the clauses (so if it one, we can satisfy all clauses)
 * and put these two variables in the objective.
 * i.e. the Objective function will be
 *
 * maximize Obj0 + Obj1
 *
 * Obj0 = MIN(Clause1, ... , Clause8)
 * Obj1 = 1 -> Clause1 + ... + Clause8 >= 4
 *
 * thus, the objective value will be two if and only if we can satisfy all
 * clauses; one if and only if at least four clauses can be satisfied, and
 * zero otherwise.

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* This example considers the following separable, convex problem:

```

```

    minimize    f(x) - y + g(z)
    subject to  x + 2 y + 3 z <= 4
                x +   y       >= 1
                x,   y,   z <= 1

    where f(u) = exp(-u) and g(u) = 2 u^2 - 4 u, for all real u. It
    formulates and solves a simpler LP model by approximating f and
    g with piecewise-linear functions. Then it transforms the model
    into a MIP by negating the approximation for f, which corresponds
    to a non-convex piecewise-linear function, and solves it again.

    Sudoku example.

```

The Sudoku board is a 9x9 grid, which is further divided into a 3x3 grid of 3x3 grids. Each cell in the grid must take a value from 0 to 9. No two grid cells in the same row, column, or 3x3 subgrid may take the same value.

In the MIP formulation, binary variables  $x[i,j,v]$  indicate whether cell  $\langle i,j \rangle$  takes value 'v'. The constraints are as follows:

1. Each cell must take exactly one value ( $\sum_v x[i,j,v] = 1$ )
2. Each value is used exactly once per row ( $\sum_i x[i,j,v] = 1$ )
3. Each value is used exactly once per column ( $\sum_j x[i,j,v] = 1$ )
4. Each value is used exactly once per 3x3 subgrid ( $\sum_{\text{grid}} x[i,j,v] = 1$ )

Input datasets for this example can be found in `examples/data/sudoku*`.

## Callback.java

```

/* Copyright 2019, Gurobi Optimization, LLC */

/*
This example reads a model from a file, sets up a callback that
monitors optimization progress and implements a custom
termination strategy, and outputs progress information to the
screen and to a log file.

The termination strategy implemented in this callback stops the
optimization of a MIP model once at least one of the following two
conditions have been satisfied:
    1) The optimality gap is less than 10%
    2) At least 10000 nodes have been explored, and an integer feasible
        solution has been found.
Note that termination is normally handled through Gurobi parameters
(MIPGap, NodeLimit, etc.). You should only use a callback for
termination if the available parameters don't capture your desired
termination criterion.

## Dense.java

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* This example formulates and solves the following simple QP model:

    minimize    x + y + x^2 + x*y + y^2 + y*z + z^2
    subject to  x + 2 y + 3 z >= 4
                x +   y      >= 1
                x, y, z non-negative

The example illustrates the use of dense matrices to store A and Q
(and dense vectors for the other relevant data). We don't recommend
that you use dense matrices, but this example may be helpful if you
already have your data in this format.

## GCPWL.java

/\* Copyright 2019, Gurobi Optimization, LLC

This example formulates and solves the following simple model  
with PWL constraints:

```

maximize
    sum c[j] * x[j]
subject to
    sum A[i,j] * x[j] <= 0,   for i = 0, ..., m-1
    sum y[j] <= 3
    y[j] = pwl(x[j]),         for j = 0, ..., n-1
    x[j] free, y[j] >= 0,     for j = 0, ..., n-1

```

where  $pwl(x) = 0$ , if  $x = 0$   
 $= 1+|x|$ , if  $x \neq 0$

Note

1.  $\text{sum } pwl(x[j]) \leq b$  is to bound  $x$  vector and also to favor sparse  $x$  vector. Here  $b = 3$  means that at most two  $x[j]$  can be nonzero and if two, then  $\text{sum } x[j] \leq 1$
2.  $pwl(x)$  jumps from 1 to 0 and from 0 to 1, if  $x$  moves from negative 0 to 0, then to positive 0, so we need three points at  $x = 0$ .  $x$  has infinite bounds on both sides, the piece defined with two points  $(-1, 2)$  and  $(0, 1)$  can extend  $x$  to  $-\infty$ . Overall we can use five points  $(-1, 2)$ ,  $(0, 1)$ ,  $(0, 0)$ ,  $(0, 1)$  and  $(1, 2)$  to define  $y = pwl(x)$

\*/

## GCPWLFunc.java

```
/* Copyright 2019, Gurobi Optimization, LLC
```

This example considers the following nonconvex nonlinear problem

```

maximize    2 x      + y
subject to  exp(x) + 4 sqrt(y) <= 9
            x, y >= 0

```

We show you two approaches to solve this:

- 1) Use a piecewise-linear approach to handle general function constraints (such as exp and sqrt).
  - a) Add two variables
 

```

u = exp(x)
v = sqrt(y)

```
  - b) Compute points (x, u) of  $u = \exp(x)$  for some step length (e.g.,  $x = 0, 1e-3, 2e-3, \dots, \text{xmax}$ ) and points (y, v) of  $v = \sqrt{y}$  for some step length (e.g.,  $y = 0, 1e-3, 2e-3, \dots, \text{ymax}$ ). We need to compute xmax and ymax (which is easy for this example, but this does not hold in general).
  - c) Use the points to add two general constraints of type piecewise-linear.

```

2) Use the Gurobis built-in general function constraints directly (EXP
and POW). Here, we do not need to compute the points and the maximal
possible values, which will be done internally by Gurobi. In this
approach, we show how to "zoom in" on the optimal solution and
tighten tolerances to improve the solution quality.

## Genconstr.java

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* In this example we show the use of general constraints for modeling
some common expressions. We use as an example a SAT-problem where we
want to see if it is possible to satisfy at least four (or all) clauses
of the logical for

L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
    (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
    (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
    (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)

We do this by introducing two variables for each literal (itself and its
negated value), a variable for each clause, and then two
variables for indicating if we can satisfy four, and another to identify
the minimum of the clauses (so if it one, we can satisfy all clauses)
and put these two variables in the objective.
i.e. the Objective function will be

maximize Obj0 + Obj1

Obj0 = MIN(Clause1, ... , Clause8)
Obj1 = 1 -> Clause1 + ... + Clause8 >= 4

thus, the objective value will be two if and only if we can satisfy all
clauses; one if and only if at least four clauses can be satisfied, and
zero otherwise.

## Multiscenario.java

```

// Copyright 2019, Gurobi Optimization, LLC

// Facility location: a company currently ships its product from 5 plants
// to 4 warehouses. It is considering closing some plants to reduce
// costs. What plant(s) should the company close, in order to minimize
// transportation and fixed costs?
//
// Since the plant fixed costs and the warehouse demands are uncertain, a
// scenario approach is chosen.
//
// Note that this example is similar to the Facility.java example. Here we
// added scenarios in order to illustrate the multi-scenario feature.
//
// Based on an example from Frontline Systems:
// http://www.solver.com/disfacility.htm
// Used with permission.

## Sudoku.java

```

/* Copyright 2019, Gurobi Optimization, LLC */
/*
Sudoku example.

The Sudoku board is a 9x9 grid, which is further divided into a 3x3 grid
of 3x3 grids. Each cell in the grid must take a value from 0 to 9.
No two grid cells in the same row, column, or 3x3 subgrid may take the
same value.

In the MIP formulation, binary variables x[i,j,v] indicate whether
cell <i,j> takes value 'v'. The constraints are as follows:
1. Each cell must take exactly one value (sum_v x[i,j,v] = 1)
2. Each value is used exactly once per row (sum_i x[i,j,v] = 1)
3. Each value is used exactly once per column (sum_j x[i,j,v] = 1)
4. Each value is used exactly once per 3x3 subgrid (sum_grid x[i,j,v] = 1)

Input datasets for this example can be found in examples/data/sudoku*.

## callback\_cs.cs

```
/* Copyright 2019, Gurobi Optimization, LLC */
```

```

/*
This example reads a model from a file, sets up a callback that
monitors optimization progress and implements a custom
termination strategy, and outputs progress information to the
screen and to a log file.

The termination strategy implemented in this callback stops the
optimization of a MIP model once at least one of the following two
conditions have been satisfied:
    1) The optimality gap is less than 10%
    2) At least 10000 nodes have been explored, and an integer feasible
       solution has been found.
Note that termination is normally handled through Gurobi parameters
(MIPGap, NodeLimit, etc.). You should only use a callback for
termination if the available parameters don't capture your desired
termination criterion.

## dense\_cs.cs

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* This example formulates and solves the following simple QP model:

    minimize    x + y + x^2 + x*y + y^2 + y*z + z^2
    subject to  x + 2 y + 3 z >= 4
                x +   y      >= 1
                x, y, z non-negative

The example illustrates the use of dense matrices to store A and Q
(and dense vectors for the other relevant data). We don't recommend
that you use dense matrices, but this example may be helpful if you
already have your data in this format.

## gc\_pwl\_cs.cs

```
/* Copyright 2019, Gurobi Optimization, LLC
```

```
This example formulates and solves the following simple model  
with PWL constraints:
```

```
maximize
    sum c[j] * x[j]
subject to
    sum A[i,j] * x[j] <= 0,   for i = 0, ..., m-1
    sum y[j] <= 3
    y[j] = pwl(x[j]),         for j = 0, ..., n-1
    x[j] free, y[j] >= 0,     for j = 0, ..., n-1
where pwl(x) = 0,           if x = 0
              = 1+|x|, if x != 0
```

Note

1.  $\text{sum pwl}(x[j]) \leq b$  is to bound  $x$  vector and also to favor sparse  $x$  vector. Here  $b = 3$  means that at most two  $x[j]$  can be nonzero and if two, then  $\text{sum } x[j] \leq 1$
2.  $\text{pwl}(x)$  jumps from 1 to 0 and from 0 to 1, if  $x$  moves from negative 0 to 0, then to positive 0, so we need three points at  $x = 0$ .  $x$  has infinite bounds on both sides, the piece defined with two points  $(-1, 2)$  and  $(0, 1)$  can extend  $x$  to  $-\infty$ . Overall we can use five points  $(-1, 2)$ ,  $(0, 1)$ ,  $(0, 0)$ ,  $(0, 1)$  and  $(1, 2)$  to define  $y = \text{pwl}(x)$

```

## gc\_pwl\_func\_cs.cs

/\* Copyright 2019, Gurobi Optimization, LLC

This example considers the following nonconvex nonlinear problem

```

maximize    2 x      + y
subject to  exp(x) + 4 sqrt(y) <= 9
            x, y >= 0

```

We show you two approaches to solve this:

- 1) Use a piecewise-linear approach to handle general function constraints (such as `exp` and `sqrt`).
  - a) Add two variables
 

```
u = exp(x)
v = sqrt(y)
```
  - b) Compute points  $(x, u)$  of  $u = \exp(x)$  for some step length (e.g.,  $x = 0, 1e-3, 2e-3, \dots, \text{xmax}$ ) and points  $(y, v)$  of  $v = \sqrt{y}$  for some step length (e.g.,  $y = 0, 1e-3, 2e-3, \dots, \text{ymax}$ ). We need to compute  $\text{xmax}$  and  $\text{ymax}$  (which is easy for this example, but this does not hold in general).
  - c) Use the points to add two general constraints of type piecewise-linear.
- 2) Use the Gurobi built-in general function constraints directly (`EXP` and `POW`). Here, we do not need to compute the points and the maximal possible values, which will be done internally by Gurobi. In this approach, we show how to "zoom in" on the optimal solution and tighten tolerances to improve the solution quality.

## genconstr\_cs.cs

```

/* Copyright 2019, Gurobi Optimization, LLC */

/* In this example we show the use of general constraints for modeling
some common expressions. We use as an example a SAT-problem where we
want to see if it is possible to satisfy at least four (or all) clauses
of the logical for

L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
    (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
    (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
    (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)

We do this by introducing two variables for each literal (itself and its
negated value), a variable for each clause, and then two
variables for indicating if we can satisfy four, and another to identify
the minimum of the clauses (so if it one, we can satisfy all clauses)
and put these two variables in the objective.
i.e. the Objective function will be

maximize Obj0 + Obj1

Obj0 = MIN(Clause1, ... , Clause8)
Obj1 = 1 -> Clause1 + ... + Clause8 >= 4

thus, the objective value will be two if and only if we can satisfy all
clauses; one if and only if at least four clauses can be satisfied, and
zero otherwise.

## sudoku\_cs.cs

```

/* Copyright 2019, Gurobi Optimization, LLC */

/*
Sudoku example.

The Sudoku board is a 9x9 grid, which is further divided into a 3x3 grid
of 3x3 grids. Each cell in the grid must take a value from 0 to 9.
No two grid cells in the same row, column, or 3x3 subgrid may take the
same value.

In the MIP formulation, binary variables x[i,j,v] indicate whether
cell <i,j> takes value 'v'. The constraints are as follows:
1. Each cell must take exactly one value (sum_v x[i,j,v] = 1)
2. Each value is used exactly once per row (sum_i x[i,j,v] = 1)
3. Each value is used exactly once per column (sum_j x[i,j,v] = 1)
4. Each value is used exactly once per 3x3 subgrid (sum_grid x[i,j,v] = 1)

Input datasets for this example can be found in examples/data/sudoku*.

## callback\_vb.vb

```

' Copyright 2019, Gurobi Optimization, LLC

' This example reads a model from a file, sets up a callback that
' monitors optimization progress and implements a custom
' termination strategy, and outputs progress information to the
' screen and to a log file.
'
' The termination strategy implemented in this callback stops the
' optimization of a MIP model once at least one of the following two
' conditions have been satisfied:
' 1) The optimality gap is less than 10%
' 2) At least 10000 nodes have been explored, and an integer feasible
'    solution has been found.
' Note that termination is normally handled through Gurobi parameters
' (MIPGap, NodeLimit, etc.). You should only use a callback for
' termination if the available parameters don't capture your desired
' termination criterion.

## dense\_vb.vb

```

' Copyright 2019, Gurobi Optimization, LLC
',
' This example formulates and solves the following simple QP model:
',
'   minimize    x + y + x^2 + x*y + y^2 + y*z + z^2
'   subject to  x + 2 y + 3 z >= 4
',
'               x +   y       >= 1
',
'               x, y, z non-negative
',
' The example illustrates the use of dense matrices to store A and Q

```

' (and dense vectors for the other relevant data). We don't recommend  
' that you use dense matrices, but this example may be helpful if you  
' already have your data in this format.

' Copyright 2019, Gurobi Optimization, LLC
'
' This example formulates and solves the following simple model
' with PWL constraints:
'
' maximize
'     sum c[j] * x[j]
' subject to
'     sum A[i,j] * x[j] <= 0,   for i = 0, ..., m-1
'     sum y[j] <= 3
'     y[j] = pwl(x[j]),        for j = 0, ..., n-1
'     x[j] free, y[j] >= 0,    for j = 0, ..., n-1
' where pwl(x) = 0,           if x = 0
'               = 1+|x|, if x != 0
'
' Note
' 1. sum pwl(x[j]) <= b is to bound x vector and also to favor sparse x vector.
'    Here b = 3 means that at most two x[j] can be nonzero and if two, then
'    sum x[j] <= 1
' 2. pwl(x) jumps from 1 to 0 and from 0 to 1, if x moves from negative 0 to 0,
'    then to positive 0, so we need three points at x = 0. x has infinite bounds
'    on both sides, the piece defined with two points (-1, 2) and (0, 1) can
'    extend x to -infinite. Overall we can use five points (-1, 2), (0, 1),
'    (0, 0), (0, 1) and (1, 2) to define y = pwl(x)

## gc\_pwl\_func\_vb.vb

```

' Copyright 2019, Gurobi Optimization, LLC
'
' This example considers the following nonconvex nonlinear problem
'
' maximize    2 x      + y
' subject to  exp(x) + 4 sqrt(y) <= 9
'             x, y >= 0
'
' We show you two approaches to solve this:
'
' 1) Use a piecewise-linear approach to handle general function
'    constraints (such as exp and sqrt).
'    a) Add two variables
'        u = exp(x)
'        v = sqrt(y)
'    b) Compute points (x, u) of u = exp(x) for some step length (e.g., x
'       = 0, 1e-3, 2e-3, ..., xmax) and points (y, v) of v = sqrt(y) for
'       some step length (e.g., y = 0, 1e-3, 2e-3, ..., ymax). We need to
'       compute xmax and ymax (which is easy for this example, but this
'       does not hold in general).
'    c) Use the points to add two general constraints of type
'       piecewise-linear.
'
' 2) Use the Gurobi's built-in general function constraints directly (EXP
'    and POW). Here, we do not need to compute the points and the maximal
'    possible values, which will be done internally by Gurobi. In this
'    approach, we show how to "zoom in" on the optimal solution and
'    tighten tolerances to improve the solution quality.

## genconstr\_vb.vb

```
' Copyright 2019, Gurobi Optimization, LLC

' In this example we show the use of general constraints for modeling
' some common expressions. We use as an example a SAT-problem where we
' want to see if it is possible to satisfy at least four (or all) clauses
' of the logical for
',
' L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
'      (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
'      (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
'      (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)
',
' We do this by introducing two variables for each literal (itself and its
' negated value), a variable for each clause, and then two
' variables for indicating if we can satisfy four, and another to identify
' the minimum of the clauses (so if it one, we can satisfy all clauses)
' and put these two variables in the objective.
' i.e. the Objective function will be
',
' maximize Obj0 + Obj1
',
' Obj0 = MIN(Clause1, ... , Clause8)
' Obj1 = 1 -> Clause1 + ... + Clause8 >= 4
',
' thus, the objective value will be two if and only if we can satisfy all
' clauses; one if and only if at least four clauses can be satisfied, and
' zero otherwise.
',

## multiscenario\_vb.vb

```

' Copyright 2019, Gurobi Optimization, LLC

' Facility location: a company currently ships its product from 5 plants
' to 4 warehouses. It is considering closing some plants to reduce
' costs. What plant(s) should the company close, in order to minimize
' transportation and fixed costs?
'
' Since the plant fixed costs and the warehouse demands are uncertain, a
' scenario approach is chosen.
'
' Note that this example is similar to the facility_vb.vb example. Here we
' added scenarios in order to illustrate the multi-scenario feature.
'
' Based on an example from Frontline Systems:
' http://www.solver.com/disfacility.htm
' Used with permission.

## sudoku\_vb.vb

```

' Copyright 2019, Gurobi Optimization, LLC
',
' Sudoku example.
',
' The Sudoku board is a 9x9 grid, which is further divided into a 3x3 grid
' of 3x3 grids. Each cell in the grid must take a value from 0 to 9.
' No two grid cells in the same row, column, or 3x3 subgrid may take the
' same value.

' In the MIP formulation, binary variables x(i,j,v) indicate whether

```

```

' cell <i,j> takes value 'v'. The constraints are as follows:
' 1. Each cell must take exactly one value (sum_v x(i,j,v) = 1)
' 2. Each value is used exactly once per row (sum_i x(i,j,v) = 1)
' 3. Each value is used exactly once per column (sum_j x(i,j,v) = 1)
' 4. Each value is used exactly once per 3x3 subgrid (sum_grid x(i,j,v) = 1)
'
' Input datasets for this example can be found in examples/data/sudoku*.

## callback.py

```

#!/usr/bin/env python3.7

# Copyright 2019, Gurobi Optimization, LLC

# This example reads a model from a file, sets up a callback that
# monitors optimization progress and implements a custom
# termination strategy, and outputs progress information to the
# screen and to a log file.
#
# The termination strategy implemented in this callback stops the
# optimization of a MIP model once at least one of the following two
# conditions have been satisfied:
# 1) The optimality gap is less than 10%
# 2) At least 10000 nodes have been explored, and an integer feasible
#    solution has been found.
# Note that termination is normally handled through Gurobi parameters
# (MIPGap, NodeLimit, etc.). You should only use a callback for
# termination if the available parameters don't capture your desired
# termination criterion.

## gc\_pwl.py

```

#!/usr/bin/env python3.7

# Copyright 2019, Gurobi Optimization, LLC

# This example formulates and solves the following simple model
# with PWL constraints:
#
# maximize
#     sum c[j] * x[j]
# subject to
#     sum A[i,j] * x[j] <= 0,   for i = 0, ..., m-1
#     sum y[j] <= 3
#     y[j] = pwl(x[j]),        for j = 0, ..., n-1
#     x[j] free, y[j] >= 0,    for j = 0, ..., n-1
# where pwl(x) = 0,           if x = 0

```

```

#             = 1+|x|, if x != 0
#
# Note
# 1. sum pwl(x[j]) <= b is to bound x vector and also to favor sparse x vector.
#    Here b = 3 means that at most two x[j] can be nonzero and if two, then
#    sum x[j] <= 1
# 2. pwl(x) jumps from 1 to 0 and from 0 to 1, if x moves from negative 0 to 0,
#    then to positive 0, so we need three points at x = 0. x has infinite bounds
#    on both sides, the piece defined with two points (-1, 2) and (0, 1) can
#    extend x to -infinite. Overall we can use five points (-1, 2), (0, 1),
#    (0, 0), (0, 1) and (1, 2) to define y = pwl(x)

## gc\_pwl\_func.py

```
#!/usr/bin/env python3.7

# Copyright 2019, Gurobi Optimization, LLC

# This example considers the following nonconvex nonlinear problem
#
# maximize      2 x      + y
# subject to    exp(x) + 4 sqrt(y) <= 9
#               x, y >= 0
#
# We show you two approaches to solve this:
#
# 1) Use a piecewise-linear approach to handle general function
#    constraints (such as exp and sqrt).
#    a) Add two variables
#        u = exp(x)
#        v = sqrt(y)
#    b) Compute points (x, u) of u = exp(x) for some step length (e.g., x
#       = 0, 1e-3, 2e-3, ..., xmax) and points (y, v) of v = sqrt(y) for
#       some step length (e.g., y = 0, 1e-3, 2e-3, ..., ymax). We need to
#       compute xmax and ymax (which is easy for this example, but this
#       does not hold in general).
#    c) Use the points to add two general constraints of type
#        piecewise-linear.
#
# 2) Use the Gurobi's built-in general function constraints directly (EXP
#    and POW). Here, we do not need to compute the points and the maximal
#    possible values, which will be done internally by Gurobi. In this
#    approach, we show how to "zoom in" on the optimal solution and
#    tighten tolerances to improve the solution quality.

## genconstr.py

```

#!/usr/bin/env python3.7

# Copyright 2019, Gurobi Optimization, LLC

# In this example we show the use of general constraints for modeling
# some common expressions. We use as an example a SAT-problem where we
# want to see if it is possible to satisfy at least four (or all) clauses
# of the logical for
#
# L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
#      (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
#      (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
#      (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)
#
# We do this by introducing two variables for each literal (itself and its
# negated value), a variable for each clause, and then two
# variables for indicating if we can satisfy four, and another to identify

```

```

# the minimum of the clauses (so if it is one, we can satisfy all clauses)
# and put these two variables in the objective.
# i.e. the Objective function will be
#
# maximize Obj0 + Obj1
#
# Obj0 = MIN(Clause1, ... , Clause8)
# Obj1 = 1 -> Clause1 + ... + Clause8 >= 4
#
# thus, the objective value will be two if and only if we can satisfy all
# clauses; one if and only if at least four clauses can be satisfied, and
# zero otherwise.

## multiscenario.py

```

#!/usr/bin/env python3.7

# Copyright 2019, Gurobi Optimization, LLC

# Facility location: a company currently ships its product from 5 plants to
# 4 warehouses. It is considering closing some plants to reduce costs. What
# plant(s) should the company close, in order to minimize transportation
# and fixed costs?
#
# Since the plant fixed costs and the warehouse demands are uncertain, a
# scenario approach is chosen.
#
# Note that this example is similar to the facility.py example. Here we
# added scenarios in order to illustrate the multi-scenario feature.

```

```

#
# Note that this example uses lists instead of dictionaries. Since
# it does not work with sparse data, lists are a reasonable option.
#
# Based on an example from Frontline Systems:
# http://www.solver.com/disfacility.htm
# Used with permission.

import gurobipy as gp

## portfolio.py

```

#!/usr/bin/env python3.7

# Copyright 2019, Gurobi Optimization, LLC

# Portfolio selection: given a sum of money to invest, one must decide how to
# spend it amongst a portfolio of financial securities. Our approach is due
# to Markowitz (1959) and looks to minimize the risk associated with the
# investment while realizing a target expected return. By varying the target,
# one can compute an 'efficient frontier', which defines the optimal portfolio
# for a given expected return.
#
# Note that this example reads historical return data from a comma-separated
# file (../data/portfolio.csv). As a result, it must be run from the Gurobi
# examples/python directory.
#
# This example requires the pandas (>= 0.20.3), NumPy, and Matplotlib
# Python packages, which are part of the SciPy ecosystem for
# mathematics, science, and engineering (http://scipy.org). These
# packages aren't included in all Python distributions, but are
# included by default with Anaconda Python.

function gc_pwl_func

% Copyright 2019, Gurobi Optimization, LLC
%
% This example considers the following nonconvex nonlinear problem
%
% maximize    2 x      + y
% subject to  exp(x) + 4 sqrt(y) <= 9
%             x, y >= 0
%
% We show you two approaches to solve this:
%
% 1) Use a piecewise-linear approach to handle general function
%    constraints (such as exp and sqrt).
%    a) Add two variables
%        u = exp(x)
%        v = sqrt(y)
%    b) Compute points (x, u) of u = exp(x) for some step length (e.g., x
%       = 0, 1e-3, 2e-3, ..., xmax) and points (y, v) of v = sqrt(y) for
%       some step length (e.g., y = 0, 1e-3, 2e-3, ..., ymax). We need to
%       compute xmax and ymax (which is easy for this example, but this
%       does not hold in general).
%    c) Use the points to add two general constraints of type
%        piecewise-linear.
%
% 2) Use the Gurobi's built-in general function constraints directly (EXP
%    and POW). Here, we do not need to compute the points and the maximal
%    possible values, which will be done internally by Gurobi. In this
%    approach, we show how to "zoom in" on the optimal solution and
%    tighten tolerances to improve the solution quality.
%

## genconstr.m

```

function genconstr()

% Copyright 2019, Gurobi Optimization, LLC
%
% In this example we show the use of general constraints for modeling
% some common expressions. We use as an example a SAT-problem where we
% want to see if it is possible to satisfy at least four (or all) clauses
% of the logical for
%
% L = (x1 or ~x2 or x3) and (x2 or ~x3 or x4) and
%      (x3 or ~x4 or x1) and (x4 or ~x1 or x2) and
%      (~x1 or ~x2 or x3) and (~x2 or ~x3 or x4) and
%      (~x3 or ~x4 or x1) and (~x4 or ~x1 or x2)
%
% We do this by introducing two variables for each literal (itself and its
% negated value), a variable for each clause, and then two
% variables for indicating if we can satisfy four, and another to identify
% the minimum of the clauses (so if it one, we can satisfy all clauses)
% and put these two variables in the objective.
% i.e. the Objective function will be
%
% maximize Obj1 + Obj2
%
% Obj1 = MIN(Clause2, ... , Clause8)
% Obj2 = 2 -> Clause2 + ... + Clause8 >= 4
%
% thus, the objective value will be two if and only if we can satisfy all
% clauses; one if and only if at least four clauses can be satisfied, and
% zero otherwise.

%LINPROG A linear programming example using the Gurobi MATLAB interface

```

```

%
% This example is based on the linprog interface defined in the
% MATLAB Optimization Toolbox. The Optimization Toolbox
% is a registered trademark of The Math Works, Inc.
%
% x = LINPROG(f,A,b) solves the linear programming problem:
%
%      minimize      f'*x
%      subject to    A*x <= b.
%
% For large problems, you can pass A as a sparse matrix and b as a
% sparse vector.
%
% x = LINPROG(f,A,b,Aeq,beq) solves the problem:
%
%      minimize      f'*x
%      subject to    A*x <= b,
%                   Aeq*x == beq.
%
% For large problems, you can pass Aeq as a sparse matrix and beq as a
% sparse vector. You can set A=[] and b=[] if no inequalities exist.
%
% x = LINPROG(f,A,b,Aeq,beq,lb,ub) solves the problem:
%
%      minimize      f'*x
%      subject to    A*x <= b,
%                   Aeq*x == beq,
%                   lb <= x <= ub.
%
% You can set lb(j) = -inf, if x(j) has no lower bound, and ub(j) = inf,
% if x(j) has no upper bound. You can set Aeq=[] and beq=[] if no
% equalities exist.
%
% x = LINPROG(f,A,b,Aeq,beq,lb,ub,OPTIONS) solves the problem above
% given the specified OPTIONS. Only a subset of possible options have
% any effect:
%
%      OPTIONS.Display 'off' or 'none' disables output,
%      OPTIONS.MaxTime time limit in seconds.
%
% You can set lb=[] or ub=[] if no bounds exist.
%
% x = LINPROG(PROBLEM) solves PROBLEM, which is a structure that must
% have solver name 'linprog' in PROBLEM.solver. You can also specify
% any of the input arguments above using fields PROBLEM.f, PROBLEM.A, ...
%
% [x,fval] = LINPROG(f,A,b) returns the objective value at the solution.
% That is, fval = f'*x.
%
% [x,fval,exitflag] = LINPROG(f,A,b) returns an exitflag containing the
% status of the optimization. The values for exitflag and the
% corresponding status codes are:
%
%      1 converged to a solution (OPTIMAL),
%      0 maximum number of iterations reached (ITERATION_LIMIT),
%     -2 no feasible point found (INFEASIBLE, NUMERIC, ...),

```

```

%      -3  problem is unbounded (UNBOUNDED).
%
%      [x,fval,exitflag,OUTPUT] = LINPROG(f,A,b) returns information about
%      the optimization. OUTPUT is a structure with the following fields:
%
%      OUTPUT.message          Gurobi status code
%      OUTPUT.constrviolation  maximum violation for constraints and bounds
%
%      [x,fval,exitflag,OUTPUT,LAMBDA] = LINPROG(f,A,b) returns the
%      Lagrangian multipliers at the solution. LAMBDA is a structure with
%      the following fields:
%
%      LAMBDA.lower           multipliers corresponding to x >= lb
%      LAMBDA.upper           multipliers corresponding to x <= ub
%      LAMBDA.ineqlin         multipliers corresponding to A*x <= b
%      LAMBDA.eqlin           multipliers corresponding to Aeq*x == beq

## feasopt.R

```

# Copyright 2019, Gurobi Optimization, LLC
#
# This example reads a MIP model from a file, adds artificial
# variables to each constraint, and then minimizes the sum of the
# artificial variables. A solution with objective zero corresponds
# to a feasible solution to the input model.
# We can also use FeasRelax feature to do it. In this example, we
# use minrelax=1, i.e. optimizing the returned model finds a solution
# that minimizes the original objective, but only from among those
# solutions that minimize the sum of the artificial variables.

# Copyright 2019, Gurobi Optimization, LLC
#
# This example formulates and solves the following simple model
# with PWL constraints:
#
# maximize
#     sum c(j) * x(j)
# subject to
#     sum A(i,j) * x(j) <= 0,   for i = 1, ..., m
#     sum y(j) <= 3
#     y(j) = pwl(x(j)),        for j = 1, ..., n
#     x(j) free, y(j) >= 0,    for j = 1, ..., n
#
# where pwl(x) = 0,          if x = 0
#               = 1+|x|, if x != 0
#
# Note
# 1. sum pwl(x(j)) <= b is to bound x vector and also to favor sparse x vector.
#    Here b = 3 means that at most two x(j) can be nonzero and if two, then
#    sum x(j) <= 1
# 2. pwl(x) jumps from 1 to 0 and from 0 to 1, if x moves from negative 0 to 0,
#    then to positive 0, so we need three points at x = 0. x has infinite bounds
#    on both sides, the piece defined with two points (-1, 2) and (0, 1) can
#    extend x to -infinite. Overall we can use five points (-1, 2), (0, 1),
#    (0, 0), (0, 1) and (1, 2) to define y = pwl(x)

## gc\_pwl\_func.R

```

# Copyright 2019, Gurobi Optimization, LLC
#
# This example considers the following nonconvex nonlinear problem
#
# maximize    2 x      + y
# subject to  exp(x) + 4 sqrt(y) <= 9
#             x, y >= 0
#
# We show you two approaches to solve this:
#
# 1) Use a piecewise-linear approach to handle general function
#    constraints (such as exp and sqrt).
#    a) Add two variables
#       u = exp(x)
#       v = sqrt(y)
#    b) Compute points (x, u) of u = exp(x) for some step length (e.g., x
#       = 0, 1e-3, 2e-3, ..., xmax) and points (y, v) of v = sqrt(y) for
#       some step length (e.g., y = 0, 1e-3, 2e-3, ..., ymax). We need to
#       compute xmax and ymax (which is easy for this example, but this
#       does not hold in general).
#    c) Use the points to add two general constraints of type
#       piecewise-linear.
#
# 2) Use the Gurobi's built-in general function constraints directly (EXP
#    and POW). Here, we do not need to compute the points and the maximal
#    possible values, which will be done internally by Gurobi. In this
#    approach, we show how to "zoom in" on the optimal solution and
#    tighten tolerances to improve the solution quality.

## genconstr.R

```
# Copyright 2019, Gurobi Optimization, LLC
#
# In this example we show the use of general constraints for modeling
# some common expressions. We use as an example a SAT-problem where we
# want to see if it is possible to satisfy at least four (or all) clauses
# of the logical for
#
# L = (x0 or ~x1 or x2) and (x1 or ~x2 or x3) and
#      (x2 or ~x3 or x0) and (x3 or ~x0 or x1) and
#      (~x0 or ~x1 or x2) and (~x1 or ~x2 or x3) and
#      (~x2 or ~x3 or x0) and (~x3 or ~x0 or x1)
#
# We do this by introducing two variables for each literal (itself and its
# negated value), a variable for each clause, and then two
# variables for indicating if we can satisfy four, and another to identify
# the minimum of the clauses (so if it one, we can satisfy all clauses)
# and put these two variables in the objective.
# i.e. the Objective function will be
#
# maximize Obj0 + Obj1
#
# Obj0 = MIN(Clause1, ... , Clause8)
# Obj1 = 1 -> Clause1 + ... + Clause8 >= 4
#
# thus, the objective value will be two if and only if we can satisfy all
# clauses; one if and only if at least four clauses can be satisfied, and
# zero otherwise.
#

## piecewise.R

```

# Copyright 2019, Gurobi Optimization, LLC
#
# This example considers the following separable, convex problem:
#
#   minimize
#       f(x) - y + g(z)
#   subject to
#       x + 2 y + 3 z   <= 4
#       x +   y         >= 1
#       x,   y,   z    <= 1
#
# where f(u) = exp(-u) and g(u) = 2 u^2 - 4u, for all real u. It
# formulates and solves a simpler LP model by approximating f and
# g with piecewise-linear functions. Then it transforms the model
# into a MIP by negating the approximation for f, which gives
# a non-convex piecewise-linear function, and solves it again.

# Copyright 2019, Gurobi Optimization, LLC */
#
# Sudoku example.
#
# The Sudoku board is a 9x9 grid, which is further divided into a 3x3 grid
# of 3x3 grids. Each cell in the grid must take a value from 0 to 9.
# No two grid cells in the same row, column, or 3x3 subgrid may take the
# same value.
#
# In the MIP formulation, binary variables x[i,j,v] indicate whether
# cell <i,j> takes value 'v'. The constraints are as follows:
# 1. Each cell must take exactly one value (sum_v x[i,j,v] = 1)
# 2. Each value is used exactly once per row (sum_i x[i,j,v] = 1)
# 3. Each value is used exactly once per column (sum_j x[i,j,v] = 1)
# 4. Each value is used exactly once per 3x3 subgrid (sum_grid x[i,j,v] = 1)
#
# Input datasets for this example can be found in examples/data/sudoku*.
